1 Linked List

We can use array to initialize the linked list as the following code. While building up the linked list from the given array, we use the **two-pointer technique** to maintain the linking between two nodes.

```
#Definition for singly-linked list.
1
    class ListNode(object):
2
        def __init__(self, x):
3
            self.val = x
             self.next = None
6
    class List(object):
8
        def __init__(self, array):
9
             if(array):
10
                 self.head = ListNode(array[0])
11
                 prev=self.head
12
                 cur = None
13
                 for i in range(1,len(array)):
14
                     cur=ListNode(array[i])
15
                     prev.next=cur
16
                     prev=cur
17
             else:
18
                 self.head = None
19
        def __str__(self):
21
             if(not self.head):
22
                 return "[]"
23
             else:
24
                 s="["
25
                 cur=self.head
26
                 while(cur):
                     s=s+str(cur.val)+" "
28
                     cur=cur.next
29
                 s=s.strip()+"]"
30
                 return s
31
32
33
    array1=[1,4,5]
34
    list1=List(array1)
    print(list1)
```

2 Sliding Widow Technique

2.1 Count distinct elements in every window of size k

Tag: Sliding Window Technique, Hashtable. See ¹.

```
Input: arr[] = {1, 2, 1, 3, 4, 2, 3}, k = 4
Output: [3, 4, 4, 3]
```

We use the sliding window to update a hashtable, which maintains the distinct elements. And the time complexity is O(n).

```
class Solution():
    '''2018-12-21
    def distinct(self,nums,k):
        if(not nums or len(nums)<k):</pre>
            return []
        d=dict()
        res=[]
        #init the first window
        for j in range(0,k):
            if(nums[j] not in d):
                d[nums[j]]=1
            else:
                d[nums[j]]+=1
        res.append(len(d))
        #update the remaining windows
        for i in range(1,len(nums)-k+1):
            #remove the first in the window, and add the last
            #to the window.
            first=nums[i-1]
            last=nums[i+k-1]
            if(d[first]==1):
                d.pop(first)
            else:
                d[first]-=1
```

¹https://www.geeksforgeeks.org/count-distinct-elements-in-every-window-of-size-k/

```
if(last not in d):
                d[last]=1
            else:
                d[last] += 1
            res.append(len(d))
        return res
    def testAll(self):
        testcase1={"nums":[1, 2, 1, 3, 4, 2, 3], "k":4, "expected":[3,4,4,3]}
        testcase2={"nums":[1, 2, 1], "k":4, "expected":[]}
        testcase3={"nums":[1, 2, 1, 3, 4, 2, 3, 5], "k":4, "expected":[3,4,4,3,4]}
        testcases=[testcase1,testcase2,testcase3]
        for testcase in testcases:
            self.test(testcase["nums"],testcase["k"],testcase["expected"])
    def test(self,nums,k,expected):
        res=self.distinct(nums,k)
        print("Test on nums=\{0\}, k=\{1\}. And \{2\} is expected, and \{3\} is got."\
                .format(nums,k,expected,res))
a=Solution()
a.testAll()
     Sliding Window Maximum (Maximum of all subarrays
2.2
     of size k)
See ^2.
```

²https://www.geeksforgeeks.org/sliding-window-maximum-maximum-of-all-

subarrays-of-size-k/

```
Input :
    arr[] = {1, 2, 3, 1, 4, 5, 2, 3, 6}
    k = 3
    Output :
    3 3 4 5 5 5 6

Input :
    arr[] = {8, 5, 10, 7, 9, 4, 15, 12, 90, 13}
    k = 4
    Output :
    10 10 10 15 15 90 90

```
class Solution():
    """2018-12-21
    """
    def maxSlidingWindow(self,nums,k):
        pass
```

3 Heap

Heap can be viewed as a complete tree, but stored as the array. Suppose the current node's index is idx, then the left child's index is 2*idx+1, and the right child 2*idx+2, while the parent floor((idx-1)/2).

We take the binary max heap as an example. The basic external function is **insert** and **extractMax**, which is implemented by **siftup** and **siftdown**. The **siftup** function check the current node's value with its parent's value, then swap them if the current node's value is bigger than the parent's, and do the check-swap operation recursively to meet the guarantee of the binary max heap.

The python source code is as following.

```
8
        def insert(self,num):
9
             if(not self.array):
10
                 self.array.append(num)
             else:
                 self.array.append(num)
13
                 self.siftup(len(self.array)-1)
14
15
16
        def siftup(self,idx):
17
             if(idx==0):
                 return
19
            parentIdx=(idx - 1) // 2
20
             if(self.array[parentIdx]<self.array[idx]):</pre>
21
                 self.array[parentIdx], self.array[idx] = \
22
                          self.array[idx], self.array[parentIdx]
23
                 return self.siftup(parentIdx)
24
25
        def extractMax(self):
26
             #swap the head (max) and the last one in self.array,
             \rightarrow then pop out the max
             if(not self.array):
28
                 raise ValueError("pop out from an empty heap")
29
30
31

    self.array[0],self.array[-1]=self.array[-1],self.array[0]
             max=self.array.pop()
             self.siftdown(0)
33
             return max
34
35
36
        def siftdown(self,idx):
37
38
             move the current node down
             if(not self.array or len(self.array)==1):
                 return
42
             left=idx*2+1
43
             right=idx*2+2
44
            maxIdx=idx
45
```

```
if(left<len(self.array) and
46
                 self.array[maxIdx]<self.array[left]):</pre>
                 maxIdx=left
47
             if(right<len(self.array) and
             → self.array[maxIdx]<self.array[right]):</pre>
                 maxIdx=right
49
50
             self.array[idx], self.array[maxIdx] =
51

→ self.array[maxIdx], self.array[idx]
             #sift down the smaller number recursively
52
             if(idx!=maxIdx):
                 self.siftdown(maxIdx)
54
55
56
        def __str__(self):
57
             s=""
58
             for i in range(len(self.array)):
59
                 if(i!=len(self.array)-1):
                     s+=str(self.array[i])+" "
61
                 else:
62
                     s+=str(self.array[i])
63
             return s
64
65
66
    heap=MaxHeap()
67
    for i in range(1,10):
68
        heap.insert(i)
69
    print("After inserting 1,2,3,4,5,6,7,8,9, the array of the
70
       heap is {0}.".format(heap))
71
    maxInHeap=heap.extractMax()
72
    print("Pop out from the heap, we'll get the maximum number
73
    \rightarrow {0}, "
           "and the array of the heap becomes
74
           → {1}.".format(maxInHeap,heap))
```

3.1 Python's heapq

We can use the library **heapq** in python. Since the default **heapq** is the min heap, so we need a trick to reimplement **MaxHeap** by overriding the

comparison function.

```
import heapq
1
    '''2018-12-24
    Use python's heapq to implement a binary max heap.
3
5
    class MaxHeapObj(object):
6
        def __init__(self, val):
7
            self.val = val
        def __lt__(self, other):
10
             return self.val > other.val
11
12
        def __eq__(self, other):
13
            return self.val == other.val
14
15
        def __str__(self):
16
            return str(self.val)
17
18
19
    class MaxHeap(object):
20
      def __init__(self):
21
          self.h = []
22
23
      def heappush(self,x):
24
          heapq.heappush(self.h,MaxHeapObj(x))
25
26
      def heappop(self):
27
          return heapq.heappop(self.h).val
28
^{29}
      def __getitem__(self,i):
30
          return self.h[i].val
31
32
      def __str__(self):
33
          s=""
34
          for e in self.h:
35
               s=s+str(e)+" "
36
          return s
37
38
```

```
39
    heap=MaxHeap()
40
41
    for i in range(1,10):
42
        heap.heappush(i)
43
44
    print("After inserting 1,2,3,4,5,6,7,8,9, the array of the
45
    → heap is {0}.".format(heap))
46
    maxInHeap=heap.heappop()
47
    print("Pop out from the heap, we'll get the maximum number
48
    \rightarrow {0}, "
           "and the array of the heap becomes
49
           → {1}.".format(maxInHeap,heap))
```

Or we can implement **MaxHeap** by multiplying -1 to each item in an array directly when using **heapq**.

```
import heapq
1
    '''2018-12-24
2
    Use python's heapq to implement a binary max heap.
    Since heapy is the min heap, so we need to reimplement
    MaxHeap by multiplying -1 to the item in min heap, and
    multiply -1 as well when using heappop() function.
6
    111
7
8
    class MaxHeap(object):
9
      def __init__(self):
10
          self.h = []
11
12
      def heappush(self,x):
13
          heapq.heappush(self.h,-x)
14
15
      def heappop(self):
16
          return heapq.heappop(self.h)*(-1)
17
18
      def __getitem__(self, i):
19
          return -1*self.h[i]
20
21
      def __str__(self):
22
          s=""
23
```

```
for i in range(len(self.h)):
24
               s=s+str(self[i])+" "
25
          return s
26
27
28
    heap=MaxHeap()
29
30
    for i in range(1,10):
31
        heap.heappush(i)
32
33
    print("After inserting 1,2,3,4,5,6,7,8,9, the array of the
    → heap is {0}.".format(heap))
35
    maxInHeap=heap.heappop()
36
    print("Pop out from the heap, we'll get the maximum number
37
    \rightarrow {0}, "
          "and the array of the heap becomes
38
           → {1}.".format(maxInHeap,heap))
```

All the above three heap codes generate the following output.

```
After inserting 1,2,3,4,5,6,7,8,9, the array of the heap \rightarrow is 9 8 6 7 3 2 5 1 4 . Pop out from the heap, we let the maximum number 9, \rightarrow and the array of the heap becomes 8 7 6 4 3 2 5 1 .
```

3.2 The application of heap

3.2.1 Merge k Sorted Lists (LeetCode 23)

Merge k sorted linked lists and return it as one sorted list. Analyze and describe its complexity³.

3.2.2 Kth Largest Element in a Stream (LeetCode 703)

Design a class to find the kth largest element in a stream. Note that it is the kth largest element in the sorted order, not the kth distinct element.

Your KthLargest class will have a constructor which accepts an integer k and an integer array nums, which contains initial elements from the stream. For each call to the method KthLargest.add, return the element representing the kth largest element in the stream.

Example:

```
int k = 3;
int[] arr = [4,5,8,2];
KthLargest kthLargest = new KthLargest(3, arr);
kthLargest.add(3);  // returns 4
kthLargest.add(5);  // returns 5
kthLargest.add(10);  // returns 5
kthLargest.add(9);  // returns 8
kthLargest.add(4);  // returns 8
```

Note:

1. You may assume that nums' length $\geq k-1$ and $k \geq 1$.

We use the min heap with the fixed size k to maintain the largest k elements in the stream. The minimum element in the min heap with size k will be the k-th largest element in a stream. The initialization of the heap is to heapify the given array. Since the time complexity of the operation of "heapify" is $O(n)^4$, so the initialization is very efficient. And the add operation in the following code is to pop out the minimum element in the array which costs $O(\log k)$. In general, the time complexity is $O(n \log k)$, where n is the size of the stream, and the space complexity is $O(\log k)$.

```
import heapq

class KthLargest(object):

2018-12-26

iii
def __init__(self, k, nums):
```

 $^{^4} https://www.growingwith$ the web.com/data-structures/binary-heap/build-heap-proof/

```
8
             :type k: int
9
             :type nums: List[int]
10
             HHHH
             #self.array is the min heap
12
             self.heap=nums
13
             heapq.heapify(self.heap)
14
             self.k=k
15
             while(len(self.heap)>k):
16
                 heapq.heappop(self.heap)
17
19
        def add(self, val):
20
21
             :type val: int
22
             :rtype: int
23
24
             if(len(self.heap) < self.k):</pre>
25
                 heapq.heappush(self.heap,val)
26
             else:
                 if(val>self.heap[0]):
28
                      #update min heap
29
                      heapq.heappop(self.heap)
30
                      heapq.heappush(self.heap,val)
31
             return self.heap[0]
32
33
    # Your KthLargest object will be instantiated and called as

    such:

    \# obj = KthLargest(k, nums)
35
    \# param_1 = obj.add(val)
36
```

3.2.3 Top K Frequent Elements (LeetCode 347)

Given a non-empty array of integers, return the k most frequent elements. Example 1:

```
Input: nums = [1,1,1,2,2,3], k = 2
Output: [1,2]
```

Example 2:

```
Input: nums = [1], k = 1
Output: [1]
```

Note:

- 1. You may assume k is always valid, $1 \le k \le$ number of unique elements.
- 2. Your algorithm's time complexity must be better than $O(n \log n)$, where n is the array's size.

4 Dynamic Programming

5 Maths

5.1 Prime numbers

5.1.1 Count Primes (LeetCode 204)

Count the number of prime numbers **less than** a non-negative number, n. Example:

```
Input: 10
Output: 4
Explanation: There are 4 prime numbers less than 10,

→ they are 2, 3, 5, 7.
```

Tag: Primes.

We use the **Sieve of Eratosthenes** to label each number within the array of $[1, \dots, n]$ is a prime or not.

```
import math
1
2
    class Solution(object):
3
         '''2018-12-15
4
         This is an O(n \log n) solution.
        def countPrimes(self, n):
8
             :type n: int
9
             :rtype: int
10
             HHHH
11
```

```
if(n<=1):
12
                 return 0
13
             #primeFlags[i]=True means the number i is a prime
14
             \rightarrow number.
             primeFlags=[True]*(n+1)
15
             primeFlags[0]=False
16
             primeFlags[1]=False
17
18
             for p in range(2,int(math.sqrt(n))+1):
19
                 if(primeFlags[p] == True):
20
                      for multiplier in range(p,n//p+1):
21
                          primeFlags[p*multiplier]=False
22
             return sum(primeFlags[:-1])
23
24
        def test(self):
25
             print("n={0}, output={1},
26

→ expected={2}".format(5,self.countPrimes(5),2))
             print("n={0}, output={1},
27

    expected={2}".format(10,self.countPrimes(10),4))

    a=Solution()
29
    a.test()
30
```

The line 18 to line 19 in the code can be optimized as the following code without the time consumption on the loop.

By eliminating the inner loop, the time consumption is reduced from 860 ms to 304 ms.

5.1.2 Ugly Number (LeetCode 263)

Write a program to check whether a given number is an ugly number.

Ugly numbers are positive numbers whose prime factors only include 2, 3, 5.

Example 1:

```
Input: 6
Output: true
Explanation: 6 = 2 * 3
```

Example 2:

```
Input: 8
Output: true
Explanation: 8 = 2 * 2 * 2
```

Example 3:

```
Input: 14
Output: false
Explanation: 14 is not ugly since it includes another

→ prime factor 7.
```

Note:

- 1. 1 is typically treated as an ugly number.
- 2. Input is within the 32-bit signed integer range: $[-2^{31}, 2^{31} 1]$.

We use the while loop to do the check and the decomposition for a given number. Since the given number is within the range $[-2^{31}, 2^{31} - 1]$, so we can do the check and the decomposition by recursion without worrying about the stack overflow (exceeding the maximum recursion depth).

```
class Solution(object):
1
         ' ' '2018-12-25
2
3
        def isUgly(self, num):
4
             :type num: int
6
             :rtype: bool
             HHHH
             if (num<1):
9
                 return False
10
11
             if (num == 1):
12
```

```
return True
13
14
             while (num > 1):
15
                  ugly = False
                  for p in [2, 3, 5]:
17
                       if (num \% p == 0):
18
                           num = num / p
19
                           ugly = True
20
                           break
21
                  if (ugly == False):
22
                      return False
23
             return True
24
25
26
    a=Solution()
27
    print(a.isUgly(2147483648))
28
       The recursion version is as following.
    class Solution(object):
1
         '''2018-12-25
2
3
         def isUgly(self, num):
              :type num: int
6
             :rtype: bool
              11 11 11
8
             def helper(num):
9
                  if(num<=0):</pre>
10
                      return False
11
                  if(num==1):
12
                      return True
13
14
                  if (num\%2==0):
15
                      return helper(num//2)
16
                  if (num\%3==0):
17
                      return helper(num//3)
                  if(num%5==0):
19
                      return helper(num//5)
20
```

return False

21

```
return helper(num)
```

5.1.3 Ugly Number II (LeetCode 264)

Write a program to find the n-th ugly number. Ugly numbers are positive numbers whose prime factors only include 2, 3, 5. Example:

Note:

22

23

- 1. 1 is typically treated as an ugly number.
- 2. n does not exceed 1690.

Tag: Maths, Primes, Tricky.

This problem's solution is very very tricky. Although the tag on this problem includes dynamic programming. But I don't think it's a good example of the dynamic programming technique, because it can not get a clear **recursive formula**. Instead, I would rather call it a tricky solution only using a tabulation.

Suppose the resulted ugly number list is F. Since F includes the numbers whose factors only include 2, 3, and 5. So we build up three lists $l_2 = 2 * F$, $l_3 = 3 * F$, and $l_5 = 5 * F$. Therefore the ugly list F has the property that $F = [1] + merge(l_2, l_3, l_5)$. Based on this property, what we should do is merging l_2 , l_3 , and l_5 . The **tricky part** is that F should be merged from l_2 , l_3 , and l_5 , while these three lists are also need to be built from F. We handle it by updating them simultaneously as the following code.

```
11 11 11
9
             F=[0]*(n+1)\#F is the list of ugly numbers
10
             F[0]=0
11
             F[1]=1
             12=[1*2] #12 is the list of 2*F
13
             13=[1*3] #13 is the list of 3*F
14
             15=[1*5] #15 is the list of 5*F
15
16
             cur2=0
17
             cur3=0
18
             cur5=0
             for i in range(2,n+1):
20
                 #update F, since F is the merge of 12, 13, and 15
21
                  \rightarrow except for 0, and 1.
                 \#So we apply the merging method to update F.
22
                 #And 12, 13, and 15 is based on F, so the update
23
                  → is simutaneously,
                 #very tricky.
24
                 F[i]=min(12[cur2],13[cur3],15[cur5])
25
26
                 #update 12, 13, and 15
27
                 12.append(F[i] * 2)
28
                 13.append(F[i] * 3)
29
                 15.append(F[i] * 5)
30
31
                 #update the pointers to 12, 13, and 15
32
                 if(F[i]==12[cur2]):
33
                      cur2+=1
34
                 if(F[i]==13[cur3]):
35
                      cur3+=1
36
                 if(F[i]==15[cur5]):
37
                      cur5+=1
38
             return F[n]
39
```

If we want to save the space of l_2 , l_3 , and l_5 , then we'll do not claim space for them but use the space of F only by maintaining the pointers in these three lists. The code is as following.

```
,,,
4
        def nthUglyNumber(self, n):
5
6
             :type n: int
             :rtype: int
8
             HHHH
9
            F=[0]*n
10
            F[0]=1
11
            n2=2 #the value of current node in 12
12
            n3=3 #the value of current node in 13
13
            n5=5 #the value of current node in 15
15
             cur2=0 #the pointer to the current node in 12
16
             cur3=0 #the pointer to the current node in 13
17
             cur5=0 #the pointer to the current node in 15
18
             for i in range(1,n):
19
                 #update F
20
                 F[i]=min(n2,n3,n5)
^{21}
22
                 #update the pointers to 12, 13, and 15
23
                 if(F[i]==n2):
24
                     cur2+=1
25
                     n2=F[cur2]*2
26
                 if(F[i]==n3):
27
                     cur3+=1
28
                     n3=F[cur3]*3
29
                 if(F[i]==n5):
30
                     cur5+=1
31
                     n5=F[cur5]*5
32
             return F[-1]
33
```

5.1.4 Super Ugly Number (LeetCode 313)

Write a program to find the nth super ugly number.

Super ugly numbers are positive numbers whose all prime factors are in the given prime list primes of size k.

Example:

Note:

- 1. 1 is a super ugly number for any given primes.
- 2. The given numbers in primes are in ascending order.
- 3. $0 < k \le 100, 0 < n \le 10^6, 0 < \text{primes[i]} < 1000.$
- 4. The nth super ugly number is guaranteed to fit in a 32-bit signed integer.

Our solution is treat this problem as the extension of the problem **Ugly Number II**. This method's time complexity is O(nk), where k is the length of the array primes. But this method is not optimized, which should be speeded up to O(nlogk). Think about the problem **Merging k Sorted Lists**, which is optimized by using the data structure heap.

```
1
    class Solution(object):
         111
2
        2018-12-25
3
         111
        def nthSuperUglyNumber(self, n, primes):
5
6
             :type n: int
             :type primes: List[int]
8
             :rtype: int
9
             11 11 11
10
             F = [1] *n
11
             pointers=[0]*len(primes)
12
             for i in range(1,n):
13
                  #merge the lists
14
                 F[i]=min([primes[j]*F[pointers[j]] for j in
15

¬ range(len(primes))])
                  #update pointers
16
```
